Package: gaussplotR (via r-universe)

October 12, 2024

October 12, 2021
Type Package
Title Fit, Predict and Plot 2D Gaussians
Version 0.2.6
Description Functions to fit two-dimensional Gaussian functions, predict values from fits, and produce plots of predicted data via either 'ggplot2' or base R plotting.
License GPL-3
Encoding UTF-8
LazyData true
Roxygen list(markdown = TRUE)
RoxygenNote 7.1.1.9000
Imports ggplot2 (>= 3.3.0), metR (>= 0.7.0), rgl, viridisLite
Suggests lattice, knitr, rmarkdown, testthat
Depends R (>= 3.3.0)

autofit_gaussian_2D characterize_gaussian_fits compare_gaussian_fits fit_gaussian_2D gaussplot_sample_data 1

2 autofit_gaussian_2D

autofit_gaussian_2D

Automatically determine the best-fitting 2D-Gaussian for a data set

Description

Automatically determine the best-fitting 2D-Gaussian for a data set

Usage

```
autofit_gaussian_2D(
  data,
  comparison_method = "rmse",
 maxiter = 1000,
  simplify = TRUE
)
```

Arguments

data

A data.frame that contains the raw data (generally rectilinearly gridded data, but this is not a strict requirement). Columns must be named "X_values", "Y_values" and "response".

comparison_method

One of "rmse", "rss", or "AIC"; what metric should be used to determine the "best-fitting" Gaussian?

maxiter Default 1000. A positive integer specifying the maximum number of iterations

allowed. See stats::nls.control() for more details.

simplify TRUE or FALSE. If TRUE, return only the coefficients, model, model_error_stats,

and fit_method for the best-fitting model. If FALSE, a model comparison table is also included in the returned list as \$model_comparison. This table is obtained

via compare_gaussian_fits().

Details

This function runs fit_gaussian_2D() three times: once for each of the "main" types of models: 1) elliptical, unconstrained; 2) elliptical, log; 3) circular. In all three cases, amplitudes and orientations are unconstrained. The function compare_gaussian_fits() is then used to determine which of these three models is the best-fitting, using the comparison_method argument to make the decision.

Value

If simplify = TRUE, a list with the components:

- "coefs" A data.frame of fitted model parameters.
- "model" The model object, fitted by stats::nls().
- "model_error_stats" A data.frame detailing the rss, rmse, deviance, and AIC of the fitted model.
- "fit_method" A character vector that indicates which method and orientation strategy was used by this function.

If simplify = FALSE, a model comparison table is also included in the returned list as \$model_comparison. This table is obtained via compare_gaussian_fits().

Author(s)

Vikram B. Baliga

Examples

```
if (interactive()) {
}
```

characterize_gaussian_fits

Characterize the orientation of fitted 2D-Gaussians

Description

The orientation and partial correlations of Gaussian data are analyzed according to Levitt et al. 1994 and Priebe et al. 2003. Features include computation of partial correlations between response variables and independent and diagonally-tuned predictions, along with Z-difference scoring.

Usage

```
characterize_gaussian_fits(
  fit_objects_list = NULL,
  data = NULL,
  constrain_amplitude = FALSE,
  ...
)
```

Arguments

fit_objects_list

A list of outputs from fit_gaussian_2D(). See Details for more. This is the preferred input object for this function.

data

A data frame that contains the raw data (generally rectilinearly gridded data, but this is not a strict requirement). Columns must be named "X_values", "Y_values" and "response". See fit_gaussian_2D() for details.

constrain_amplitude

Default FALSE; should the amplitude of the Gaussian be set to the maximum value of the "response" variable (TRUE), or should the amplitude fitted by stats::nls() (FALSE)? See fit_gaussian_2D() for details.

... Additional arguments that can be passed to fit_gaussian_2D() if data are supplied.

Details

This function accepts either a list of objects output from fit_gaussian_2D() (preferred) or a data.frame that contains the raw data.

The supplied fit_objects_list must be a list that contains objects returned by fit_gaussian_2D(). This list must contain exactly three models. All three models must have been run using method = "elliptical_log". The models must be: 1) one in which orientation is unconstrained, 2) one in which orientation is constrained to Q = 0 (i.e. a diagonally-oriented Gaussian), and 3) one in which orientation is constrained to Q = -1 (i.e. a horizontally-oriented Gaussian). See this function's Examples for guidance.

Should raw data be provided instead of the fit_objects_list, the characterize_gaussian_fits() runs fit_gaussian_2D() internally. This is generally not recommended, as difficulties in fitting models via stats::nls() are more easily troubleshot by the optional arguments in fit_gaussian_2D(). Nevertheless, supplying raw data instead of a list of fitted models is feasible, though your mileage may vary.

Value

A list with the following:

- "model_comparison" A model comparison output (i.e. what is produced by compare_gaussian_fits()), which indicates the relative preference of each of the three models.
- "Q_table" A data.frame that provides information on the value of Q from the best-fitting model, along with the 5-95% confidence intervals of this estimate.
- " r_i " A numeric, the correlation of the data with the independent (Q = -1) prediction.
- "r_s" A numeric, the correlation of the data with the diagonally- oriented (Q = 0) prediction.
- "r_is" A numeric, the correlation between the independent (Q = -1) prediction and the the diagonally-oriented (Q = 0) prediction.
- "R_indp" A numeric, partial correlation of the response variable with the independent (Q = -1) prediction.
- "R_diag" A numeric, partial correlation of the response variable with the diagonally-oriented (Q = 0) prediction.

- "ZF_indp" A numeric, the Fisher Z-transform of the R_indp coefficient. See Winship et al. 2006 for details.
- "ZF_diag" A numeric, the Fisher Z-transform of the R_diag coefficient. See Winship et al. 2006 for details.
- "Z_diff" A numeric, the Z-difference between ZF_indp and ZF_diag. See Winship et al. 2006 for details.

compare_gaussian_fits Compare fitted 2D-Gaussians and determine the best-fitting model

Description

Compare fitted 2D-Gaussians and determine the best-fitting model

Usage

```
compare_gaussian_fits(fit_objects_list, comparison_method = "rmse")
```

Arguments

```
\label{list-def} A \ list of outputs from fit\_gaussian\_2D(). \ See \ Details for more \\ comparison\_method
```

One of "rmse", "rss", or "AIC"; what metric should be used to determine the "best-fitting" Gaussian?

Details

For the argument fit_objects_list, a list of fitted model objects (output from fit_gaussian_2D()) can simply be combined via list(). Naming the list is optional; should you supply names, the output of compare_gaussian_fits() will refer to specific models by these names.

Value

A list with the components:

- "preferred_model" A character indicating the name of the preferred model (or if a named list was not provided, a model number is given in the order of the original supplied list).
- "comparison_table" A data.frame detailing the rss, rmse, deviance, , AIC, R2, and adjusted R2 of the fitted models. The data.frame is sorted by the comparison_method that was selected.

```
)
}
```

fit_gaussian_2D

Determine the best-fit parameters for a specific 2D-Gaussian model

Description

Determine the best-fit parameters for a specific 2D-Gaussian model

Usage

```
fit_gaussian_2D(
  data,
 method = "elliptical",
 constrain_amplitude = FALSE,
  constrain_orientation = "unconstrained",
  user_init = NULL,
 maxiter = 1000,
  verbose = FALSE,
  print_initial_params = FALSE,
)
```

Arguments

data

A data.frame that contains the raw data (generally rectilinearly gridded data, but this is not a strict requirement). Columns must be named "X_values", "Y_values" and "response".

method

Choice of "elliptical", "elliptical_log", or "circular". Determine which specific implementation of 2D-Gaussian to use. See Details for more.

constrain_amplitude

Default FALSE; should the amplitude of the Gaussian be set to the maximum value of the "response" variable (TRUE), or should the amplitude fitted by stats::nls()(FALSE)?

constrain_orientation

If using "elliptical" or method = "elliptical_log", should the orientation of the Gaussian be unconstrained (i.e. the best-fit orientation is returned) or should it be pre-set by the user? See Details for more. Defaults to "unconstrained".

user_init

Default NULL; if desired, the user can supply initial values for the parameters of the chosen model. See Details for more.

maxiter

Default 1000. A positive integer specifying the maximum number of iterations allowed. See stats::nls.control() for more details.

verbose

TRUE or FALSE; should the trace of the iteration be printed? See the trace argument of stats::nls() for more detail.

fit_gaussian_2D 9

print_initial_params

TRUE or FALSE; should the set of initial parameters supplied to stats::nls() be printed to the console? Set to FALSE by default to avoid confusion with the fitted parameters attained after using stats::nls().

... Additional arguments passed to stats::nls.control()

Details

stats::nls() is used to fit parameters for a 2D-Gaussian to the supplied data. Each method uses (slightly) different sets of parameters. Note that for a small (but non-trivial) proportion of data sets, nonlinear least squares may fail due to singularities or other issues. Most often, this occurs because of the starting parameters that are fed in. By default, this function attempts to set default parameters by making an educated guess about the major aspects of the supplied data. Should this strategy fail, the user can make use of the user_init argument to supply an alternate set of starting values.

The simplest method is method = "circular". Here, the 2D-Gaussian is constrained to have a roughly circular shape (i.e. spread in X- and Y- are roughly equal). If this method is used, the fitted parameters are: Amp (amplitude), X_peak (x-axis peak location), Y_peak (y-axis peak location), X_sig (spread along x-axis), and Y_sig (spread along y-axis).

A more generic method (and the default) is method = "elliptical". This allows the fitted 2D-Gaussian to take a more ellipsoid shape (but note that method = "circular" can be considered a special case of this). If this method is used, the fitted parameters are: A_o (a constant term), Amp (amplitude), theta (rotation, in radians, from the x-axis in the clockwise direction), X_peak (x-axis peak location), Y_peak (y-axis peak location), a (width of Gaussian along x-axis), and b (width of Gaussian along y-axis).

A third method is method = "elliptical_log". This is a further special case in which log2-transformed data may be used. See Priebe et al. 2003 for more details. Parameters from this model include: Amp (amplitude), Q (orientation parameter), X_peak (x-axis peak location), Y_peak (y-axis peak location), X_sig (spread along x-axis), and Y_sig (spread along y-axis).

If using either method = "elliptical" or method = "elliptical_log", the "constrain_orientation" argument can be used to specify how the orientation is set. In most cases, the user should use the default "unconstrained" setting for this argument. Doing so will provide the best-fit 2D-Gaussian (assuming that the solution yielded by stats::nls() converges on the global optimum).

Setting constrain_orientation to a numeric (e.g. constrain_orientation = pi/2) will force the orientation of the Gaussian to the specified value. Note that this is handled differently by method = "elliptical" vs method = "elliptical_log". In method = "elliptical", the theta parameter dictates the rotation, in radians, from the x-axis in the clockwise direction. In contrast, the method = "elliptical_log" procedure uses a Q parameter to determine the orientation of the 2D-Gaussian. Setting constrain_orientation = 0 will result in a diagonally-oriented Gaussian, whereas setting constrain_orientation = -1 will result in horizontal orientation. See Priebe et al. 2003 for more details.

The user_init argument can also be used to supply a vector of initial values for the A, Q, X_peak, Y_peak, X_var, and Y_var parameters. If the user chooses to make use of user_init, then a vector containing all parameters must be supplied in a particular order.

Additional arguments to the control argument in stats::nls() can be supplied via

10 fit_gaussian_2D

Value

A list with the components:

- "coefs" A data.frame of fitted model parameters.
- "model" The model object, fitted by stats::nls().
- "model_error_stats" A data.frame detailing the rss, rmse, deviance, AIC, R2 and adjusted R2 of the fitted model.
- "fit_method" A character vector that indicates which method and orientation strategy was used by this function.

gaussplot_sample_data Sample data set

Description

A data. frame of raw data and fitted 2D-Gaussian parameters; intended for use with predict_gaussian_2D()

Usage

```
gaussplot_sample_data
```

Format

A data frame with 36 rows and 11 variables:

X_values vector of numeric values for the x-axis

Y_values vector of numeric values for the y-axis

response vector of numeric values for the response variable

norm_g_resp normalized values from the 2D-Gaussian fit

g_resp values from the 2D-Gaussian fit

A amplitude of 2D-Gaussian (repeated)

X_peak location of peak x-axis value (repeated)

X_var variance in x (repeated)

Q orientation parameter of the gaussian (repeated)

Y_peak location of peak y-axis value (repeated)

Y_var variance in y (repeated)

get_volume_gaussian_2D

Compute volume under 2D-Gaussian

Description

Compute volume under 2D-Gaussian

Usage

```
get_volume_gaussian_2D(X_sig, Y_sig)
```

Arguments

X_sig numeric value(s) of the x-axis spread (sigma)
Y_sig numeric value(s) of the y-axis spread (sigma)

Details

Volume under the 2D-Gaussian is computed as: 2 * pi * sqrt(abs(X_sig)) * sqrt(abs(Y_sig))

Numeric vectors can be supplied to X_sig and Y_sig. If vectors of length greater than 1 are given, the function computes volume for each sequential pair of X_sig, Y_sig values. The lengths of these supplied vectors must be identical.

Value

Numeric value(s) indicating the computed volume(s)

Author(s)

Vikram B. Baliga

ggplot_gaussian_2D 13

Examples

```
library(gaussplotR)
get_volume_gaussian_2D(5, 3) #24.33467
```

ggplot_gaussian_2D

Plot a 2D-Gaussian via ggplot

Description

Plot a 2D-Gaussian via ggplot

Usage

```
ggplot_gaussian_2D(
  gauss_data,
  normalize = TRUE,
  contour_thickness = 0.04,
  contour_color = "black",
  bins = 15,
  viridis_dir = 1,
  viridis_opt = "B",
  x_lab = "X values",
  y_lab = "Y values",
  axis.text = element_text(size = 6),
  axis.title = element_text(size = 7),
  axis.ticks = element_line(size = 0.3),
  plot.margin = unit(c(0.1, 0.1, 0.1, 0.1), "cm"),
  ...
)
```

Arguments

gauss_data	Data.frame with X_values, Y_values, and predicted_values, e.g. exported from predict_gaussian_2D()
normalize	Default TRUE, should predicted_values be normalized on a 0 to 1 scale?
contour_thickness	
	Thickness of contour lines
contour_color	Color of the contour lines
bins	Number of bins for the contour plot
viridis_dir	See "direction" in scale_fill_viridis_c()
viridis_opt	See "option" in scale_fill_viridis_c()
x_lab	Arguments passed to xlab()
y_lab	Arguments passed to ylab()

```
axis.text Arguments passed to axis.text

axis.title Arguments passed to axis.title

axis.ticks Arguments passed to axis.ticks

plot.margin Arguments passed to plot.margin

Other arguments supplied to ggplot2::theme()
```

Value

A ggplot object that uses metR::geom_contour_fill() to display the 2D-Gaussian

Author(s)

Vikram B. Baliga

```
if (interactive()) {

 ## Plot via ggplot2 and metR
 ggplot_gaussian_2D(gauss_data)
 ## Produce a 3D plot via rgl
 rgl_gaussian_2D(gauss_data)
}
```

Description

Predict values from a fitted 2D-Gaussian

Usage

```
predict_gaussian_2D(fit_object, X_values, Y_values, ...)
```

Arguments

```
Fit_object Either the output of gaussplotR::fit_gaussian_2D() or a list that contains coefficients and fit methods (see Details).

X_values vector of numeric values for the x-axis

Y_values vector of numeric values for the y-axis

Additional arguments
```

Details

This function assumes Gaussian parameters have been fitted beforehand. No fitting of parameters is done within this function; these can be supplied via the object created by gaussplotR::fit_gaussian_2D().

If fit_object is not an object created by gaussplotR::fit_gaussian_2D(), predict_gaussian_2D() attempts to parse fit_object as a list of two items. The coefficients of the fit must be supplied as a one-row, named data.frame within fit_object\$coefs, and details of the methods for fitting the Gaussian must be contained as a character vector in fit_object\$fit_method. This character vector in fit_object\$fit_method must be a named vector that provides information about the method, amplitude constraint choice, and orientation constraint choice, using the names method, amplitude, and orientation. method must be one of: "elliptical", "elliptical_log", or "circular". amplitude and orientation must each be either "unconstrained" or "constrained". For example, c(method = "elliptical", amplitude = "unconstrained", orientation = "unconstrained"). One exception to this is when method = "circular", in which case orientation must be NA, e.g.: c(method = "circular", amplitude = "unconstrained", orientation = NA).

Value

A data.frame with the supplied X_values and Y_values along with the predicted values of the 2D-Gaussian (predicted_values)

 grid <-
    expand.grid(X_values = seq(from = -5, to = 0, by = 0.1),
                Y_{\text{values}} = \text{seq(from} = -1, to = 4, by = 0.1))
 ## Predict the values using predict_gaussian_2D
 gauss_data <-
   predict_gaussian_2D(
      fit_object = gauss_fit,
      X_values = grid$X_values,
      Y_values = grid$Y_values,
   )
 ## Plot via ggplot2 and metR
 ggplot_gaussian_2D(gauss_data)
 ## Produce a 3D plot via rgl
 rgl_gaussian_2D(gauss_data)
}
```

rgl_gaussian_2D

Produce a 3D plot of the 2D-Gaussian via rgl

Description

Produce a 3D plot of the 2D-Gaussian via rgl

Usage

```
rgl_gaussian_2D(
```

18 rgl_gaussian_2D

```
gauss_data,
normalize = TRUE,
viridis_dir = 1,
viridis_opt = "B",
x_lab = "X values",
y_lab = "Y values",
box = FALSE,
aspect = TRUE,
...
)
```

Arguments

```
gauss_data
                  Data.frame with X_values, Y_values, and predicted_values, e.g. exported from
                  predict_gaussian_2D()
normalize
                  Default TRUE, should predicted_values be normalized on a 0 to 1 scale?
viridis_dir
                  See "direction" in scale_fill_viridis_c()
viridis_opt
                  See "option" in scale_fill_viridis_c()
x_lab
                  Arguments passed to xlab()
y_lab
                  Arguments passed to ylab()
box
                  Whether to draw a box; see rgl::plot3d()
                  Whether to adjust the aspect ratio; see rgl::plot3d()
aspect
                  Other arguments supplied to rgl::plot3d()
. . .
```

Value

An rgl object (i.e. of the class 'rglHighlevel'). See rgl::plot3d() for details.
